source("http://highstat.com/Books/BGS/GAMM/RCodeP2/HighstatLibV6.R")
# (generalized) Linear mixed modeling
library(lme4)
library(glmmTMB)
library(lmodel2)
# Statistical analysis reporting and model validation
library(performance)
library(car)
library(lmtest)
library(DHARMA)
# Data wrangling
library(dplyr)
library(plyr)
library(tidyverse)
library(tidylog)
library(splancs)
```

## 1.4 Load in dataframe

```
# Loading in data set
IndBehav <- read_csv("VIEBehavior_20210913_V2.csv", col_types = cols(fishID = col_character(),
  Infection = col_character(), InfDate = col_character(), BehavGroup = col_character(),
  dayofinf = col_character(), CountDay = col_character(), Behavdate = col_character(),
  TOD = col_character(), Duration = col_double(), Velocity = col_double(), Distance = col_double()))

# Filtering Data set so we can perform our analysis
IndBehav1 <- IndBehav %>%
  # Removing columns we dont need
select(-c(Blind.ID, InfLength, LateLength, dayofinf, Countintial, Notes, InfWeight))
```

```
## select: dropped 7 variables (Blind.ID, InfWeight, InfLength, LateLength, dayofinf, ...)
```

```
# Quickly checking whether individuals have stress response from a new
# environment.
```

```
# Filter to only before measurements
IndBehav1_Before <- IndBehav1 %>%
  filter(TrialTime == "Before")
```

```
## filter: removed 829 rows (75%), 276 rows remaining
```

```
# plot the velocity by time of day
```

```
ggplot(IndBehav1_Before, aes(x = TOD, y = Velocity, fill = Sex)) + geom_boxplot(aes(fill = Sex)) +
  geom_jitter() + theme_classic()
```

```
# Quick Anova to verify that the difference is significantly different
```

```
anova(lm(Velocity ~ TOD * Sex, IndBehav1_Before))
```

```
## Analysis of Variance Table
```

```
##
```

```
## Response: Velocity
```

```

IndBehav2 <- rbind(FemaleOnly, MaleOnly)

# View(IndBehav2)
```

### 1.6.2 Checking that fish velocity is not different at different times of day.

We recorded the velocity of the fish at 3 time periods over the course of the day. Once in the morning between 0900-1100, once in the afternoon 1200-1400, 1500-1700. Therefore we wanted to confirm that there is no consistent Time of day effect before we collapse the behavioral measurements into means for each day.

```
##### First visually look at the TOD effect for behavior#####
ggplot(IndBehav2, aes(TOD, Velocity)) + geom_boxplot() + geom_jitter() + xlab("Time of Day") +
  ylab("Velocity (cm/s)") + theme_classic()
```

```
#### Verify that this is not statistically significant####
anova(lm(Velocity ~ TOD, IndBehav2))
```

```
## Analysis of Variance Table
##
## Response: Velocity
##           Df Sum Sq Mean Sq F value Pr(>F)
## TOD         2    5.55  2.77265   2.8353 0.05921 .
## Residuals 927 906.51  0.97789
## ---
## Signif. codes:  0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1
```

```
##### Lets also confirm this does not change by sex#####
ggplot(IndBehav2, aes(TOD, Velocity, fill = Sex)) + geom_boxplot() + geom_jitter() +
  xlab("Time of Day") + ylab("Velocity (cm/s)") + theme_classic()
```

```
##### Lets also confirm this does not change by Infection Status#####
ggplot(IndBehav2, aes(TOD, Velocity, fill = Infection)) + geom_boxplot() + geom_jitter() +
  xlab("Time of Day") + ylab("Velocity (cm/s)") + theme_classic()
```

Visually there does not seem to be a distinguished pattern overall and an anova confirms it. It also does not seem to visually differ by sex or infection status. Therefore we can collapse the three different time points within a day to a mean velocity and variance of velocity across each time point, Before, Early, Late, and Later.

### 1.6.3 Calculating the behavioral tolerance metrics needed for analyses

We are calculating behavioral tolerance through two metrics. First is a measure of behavioral tolerance using linear mixed models using slope random effects for fishID. This allows us to extract each individuals change in activity with parasite burden and therefore allow us to calculate the tolerance (fishID slope) for each individual. This also allows us to use the random effect intercept for fishID as a measure of behavioral vigor. The second way we could calculate these metrics are a measure of change in behavior between two points of behavior (often referred to as point tolerance, CITATION FOR THIS). This is calculated in the second half of the code as the change in behavior between pre-infection and early, late, and later points of infection.

```
# Calculating the behavioral tolerance metrics were interested in for our
# analysis

# Random slope from random effects model Random effects model with random slope
# for each fish by worm burden prior to measuring its activity. This slope is
# the tolerance an individual has to changing its behavior as infection
# increases. The slope of the behavior is the individuals behavioral vigor, or
# its pre-infection behavior#####
BehavTolLM <- lmer(Velocity ~ (Wormbf | fishID), IndBehav2)
summary(BehavTolLM)

```

Now we have to decide how best to calculate whether an individual has recovered. In the experiment only 13 fish recover from infection totally, therefore we are thinking of another metric that indicates a fish is in recovery during infection.

**AvgVel:** The average velocity from three separate behavioral trials of each fish for each of the Trial Times.

(*cm/s*)

**Sex:** The sex of the individual. F - female, M - male

**PreWeight:** The weight of the individual prior to their first behavior trial and pre-infection. (*grams*)

**PreLength:** The length of the individual prior to their first behavior trial and pre-infection (*mm*)

**Treatment:** What treatment the fish received prior to their first behavior and pre-infection. VIE - visible implant elastomer implant, UNTOUCHED - control individual, received no injection nor implant (*mm*)

**Infection:** Whether or not the individual was infected with *Gyrodactylus turnbulli*. 1 - infected, 0 - uninfected

**LateWeight:** The weight of the individual after their final behavior trial and after infection. (*grams*)

**wormJump:** The number of worms that jumped from the donor fish to the trial fish during manual infections.

**AUC2:** The area under the curve of infection over the total infection trajectory for each individual.

**RecovPeriod:** The time frame in which an individual started recovering from infection. This is calculated by looking at the growth rate of the worms between each count and see when the worm growth rate was decreasing overall.

**ContInf:** Whether or not the individual was controlling infection. We qualified controlling infection by having a negative growth rate post peak infection. 1 - Controlled, 0 - Uncontrolled

**Died:** Whether or not the individual Died from infection during the experimental trial. 1 - Died, 0 - did not die

**PreSMI:** The body condition of the individual prior to their first behavioral trial and pre infection. (*mm/g*)

**LateSMI:** The body condition of the individual after to their last behavioral trial and after infection. (*mm/g*)

**Wormbf:** The number of worms on the fish prior to each trial.

**Ratebf:** The rate of growth of worms on the fish prior to each trial from the worm count immediately prior to the trial.

**NRatebf:** The rate of growth of worms on the fish prior to each trial calculated as the change in worms between each time point. (For Example, From before to early).

**VarVel:** The variance in velocity from the separate behavioral trials during each time point. ( $(cm/s)^2$ )

**BehavTol:** The behavioral tolerance of each individual calculated as the slope of a random effect model where fishID is the random effect term.

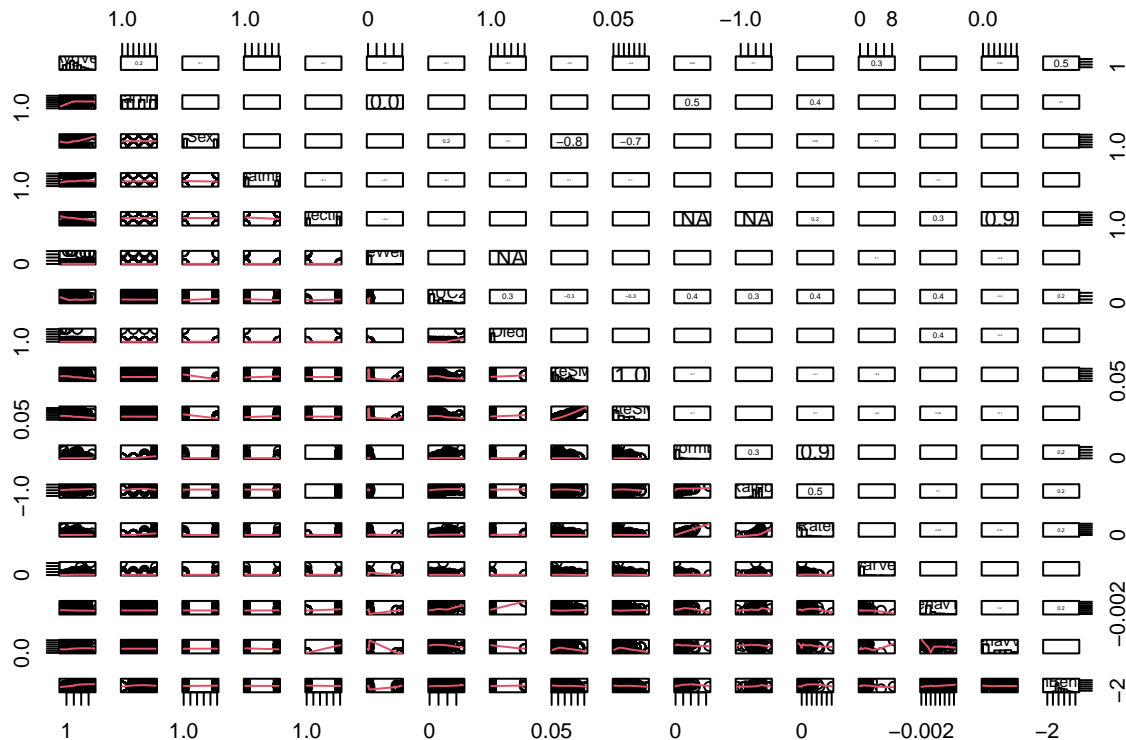

**BehavVig:** The behavioral Vigor of each individual calculated as the intercept of a random effect model where fishID is the random effect term

**ChBehav:** The change in behavior between trial times. (*cm/s*)

**PTol:** Point tolerance metric calculated by dividing the change in behavior between time points by the worms on the fish before the trial (*cm/s/worms*)

## 1.8 Visualizing the relationships between variables in our dataset

```
pairs(~AvgVel + TrialTime + Sex + Treatment + Infection + LateWeight + AUC2 + Died +

## 2.1 What hypotheses we want to test with these data and what data we can use to test them?

For uninfected and infected individuals only:

Do infected and uninfected individuals differ in their average and variation in velocity?

Is there sexual variation in the average and variation in velocity?

Do we see differences in the change in behavior and between infected

For infected individuals only:

Does activity predict the intensity of infection?

Is there sexual variation in host behavioral tolerance and behavioral vigor?

Do host behavioral tolerance, tissue tolerance, and behavioral vigor correlate together and does this differ by sex?

Do hosts with lower behavioral tolerance have higher behavior resilience (i.e. how hosts behave once they have started to clear infection/have cleared infection)

Is there sexual variation in individuals behavioral resilience?

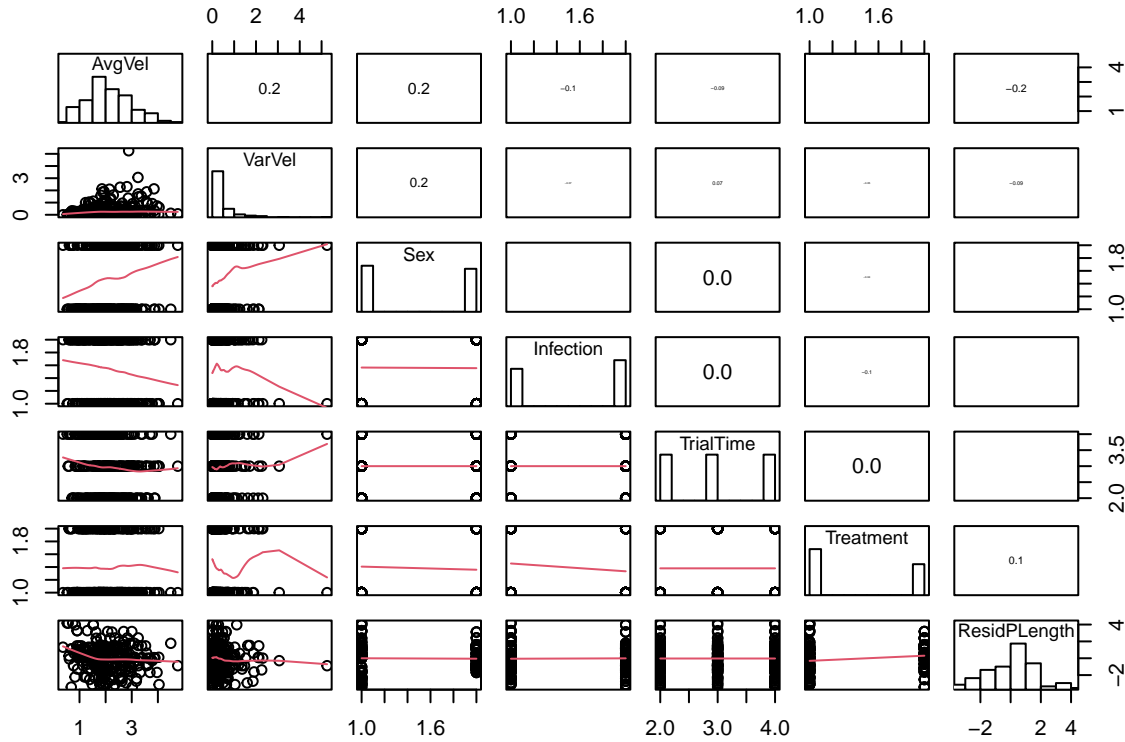

polygon area as resilience and how this relates to other metrics

### 3 Do infected and uninfected individuals differ in their average and variation in velocity?

#### 3.1 Visually inspection of the explanatory variables that will be used in the analyses

```
pairs(~AvgVel + VarVel + Sex + Infection + TrialTime + Treatment + ResidPLength,  
      lower.panel = panel.smooth, diag.panel = panel.hist, upper.panel = panel.cor,  
      data = IndBehav8)
```

#### 3.2 Does infection or sex variation impact the average velocity of individuals?

Individuals had 3 behavioral trials per time period of infection (i.e. 3 behavioral trials before infection) and therefore using preliminary analysis we showed that there is no difference due to time of day of these recordings so we averaged and quantified the variance of the velocities for that day to get an average velocity per trial time.

This analysis uses the average velocity for each individual at each trial point.

##### 3.2.1 Description, development, and fitting of linear model for the analysis

We will use a linear mixed model to analyze how average velocity differs by infection status and sexual variation. FishID is included as a random term to allow for non-independence of individuals due to multiple measurements per individual across time.

- Deterministic

- $AvgVel_{det} = a + b_1 TrialTime + b_2 Infection * b_3 Sex + b_4 ScPSMI + b_5 ScRPLength + b_6 Treatment + a_i$
- Stochastic
  - $AvgVel \sim N(AvgVel_{det}, \sigma^2)$
  - $a_i \sim N(0, \sigma_{fishID}^2)$
- Fixed
  - TrialTime
  - Infection status
  - Sex
  - An interaction between Sex and Infection status
  - Scaled Pre-infection SMI
  - Scaled residuals from length and sex
  - VIE Treatment
- Random
  - fishID

```
# Fit a linear model for checking what explanatory factors are important for
# Average Velocity Note this is a linear mixed model because we have multiple
# measures per fish and therefore, need to account for non-independence between
# measures.

## 5.6 What factors are important for the change of hosts behavior over fitness space and ifnection?

### 5.6.1 Description, development, and fitting of linear model for the analysis

We will use a linear model to analyze how host total movement over fitness space differs by sexual variation and other important host traits. Given each host only has one total movement over fitness space measure, we do not need the fishID random effect used in previous models.

- Deterministic
- $PolyArea_{det} = a + b_1Sex + b_2ScPSMI + b_3ScVarVelBef + b_4ScBehavVig$
- Stochastic
  - $PolyArea \sim N(PolyArea_{det}, \sigma^2)$
- Fixed
  - Sex
  - Scaled Pre-infection SMI
  - Scaled variance in velocity before infection
  - Scaled behavioral vigor
